Efficiency test of priority vectors derived from 4×4 pairwise comparison matrices

Ádám ANTAL¹, Sándor BOZÓKI^{2,3,4}

Abstract

Three weighting methods, the eigenvector, the arithmetic mean of all spanning trees' weight vectors (AMAST) and the cosine maximization have been investigated in case of 4×4 pairwise comparison matrices, with elements chosen from the usual ratio scale $1, 2, \dots, 9, 1/2, 1/3, \dots, 1/9$. Out of the 32 157 permutation filtered matrices fulfilling the rule of acceptable inconsistency ($CR \leq 0.1$), 591 (1.84%); 197 (0.61%) and 602 (1.87%) have inefficient eigenvector, AMAST and cosine maximizing weight vector, respectively. All these examples are listed in the appendix.

Keywords: multiple criteria analysis, decision support, pairwise comparison matrix, Pareto optimality, efficiency, eigenvector, spanning trees, cosine similarity

1 Introduction

1.1 Efficiency of weight vectors derived from pairwise comparison matrices

Preference modelling, especially the quantification of decision maker's preferences is fundamental in decision theory and decision support. We focus on decision models based on cardinal information originated from comparisons of two objects at a time. A positive and reciprocal ($a_{ij} = 1/a_{ji}$ for all i, j) matrix is called a pairwise comparison matrix [20]. The matrix element a_{ij} reflects the decision maker's preference on a ratio scale when item (typically the importance of a criterion, or the performance of action) i is compared to item j .

Let \mathbf{A} be a pairwise comparison matrix of size $n \times n$ and $\mathbf{w}, \mathbf{w}' \in \mathbb{R}^n$ be positive weight vectors.

Itt nem kéne definiálni, hogy mi az a weight vector? (nem elég csak annyit írni, hogy vector, vagy hogy a továbbiakban az egyszerű vektorokra mint súlyvektorokra szeretnénk tekinteni)

Definition 1.1. Weight vector $\mathbf{w}' = (w'_1, w'_2, \dots, w'_n)^\top$ dominates weight vector \mathbf{w} if

$$\left| a_{ij} - \frac{w'_i}{w'_j} \right| \leq \left| a_{ij} - \frac{w_i}{w_j} \right| \quad \text{for all } 1 \leq i, j \leq n, \quad (1)$$

$$\left| a_{k\ell} - \frac{w'_k}{w'_\ell} \right| < \left| a_{k\ell} - \frac{w_k}{w_\ell} \right| \quad \text{for some } 1 \leq k, \ell \leq n. \quad (2)$$

If weight vector \mathbf{w} cannot be dominated, then it is called *efficient*, otherwise it is called *inefficient*.

Definition 1.2. Weight vector $\mathbf{w}' = (w'_1, w'_2, \dots, w'_n)^\top$ internally dominates weight vector \mathbf{w} if

$$\left. \begin{aligned} a_{ij} \leq \frac{w_i}{w_j} &\implies a_{ij} \leq \frac{w'_i}{w'_j} \leq \frac{w_i}{w_j} \\ a_{ij} \geq \frac{w_i}{w_j} &\implies a_{ij} \geq \frac{w'_i}{w'_j} \geq \frac{w_i}{w_j} \end{aligned} \right\} \quad \text{for all } 1 \leq i, j \leq n, \quad (3)$$

$$\left. \begin{aligned} a_{k\ell} \leq \frac{w_k}{w_\ell} &\implies \frac{w'_k}{w'_\ell} < \frac{w_k}{w_\ell} \\ a_{k\ell} \geq \frac{w_k}{w_\ell} &\implies \frac{w'_k}{w'_\ell} > \frac{w_k}{w_\ell} \end{aligned} \right\} \quad \text{for some } 1 \leq k, \ell \leq n. \quad (4)$$

If weight vector \mathbf{w} cannot be internally dominated, then it is called *internally efficient*, otherwise it is called *internally inefficient*.

Efficiency implies internal efficiency by definition, but they are in fact equivalent [4, Corollary 1]. Definitions also imply that efficiency is scale invariant: weight vector \mathbf{w} is efficient if and only if $c\mathbf{w}$ is efficient, where $c > 0$ is arbitrary. Ratios $\frac{w_i}{w_j}$ and $\frac{cw_i}{cw_j}$ are clearly equal.

A dominating weight vector \mathbf{w}' , if it exists, can be found by solving the following linear program, developed by Bozóki and Fülöp [4, formulas (26)-(31)]:

$$\min \sum_{(i,j): a_{ij} < \frac{w_i}{w_j}} -s_{ij} \quad (5)$$

$$y_j - y_i \leq -\log a_{ij} \quad \text{for all } (i, j) \text{ such that } a_{ij} < \frac{w_i}{w_j}, \quad (6)$$

$$y_i - y_j + s_{ij} \leq \log w_i - \log w_j \quad \text{for all } (i, j) \text{ such that } a_{ij} < \frac{w_i}{w_j}, \quad (7)$$

$$y_i - y_j = \log a_{ij} \quad \text{for all } (i, j) \text{ such that } a_{ij} = \frac{w_i}{w_j}, \quad (8)$$

$$s_{ij} \geq 0 \quad \text{for all } (i, j) \text{ such that } a_{ij} < \frac{w_i}{w_j}, \quad (9)$$

$$y_1 = 0 \quad (10)$$

Variables are y_i , $1 \leq i \leq n$ and s_{ij} for all (i, j) such that $a_{ij} < \frac{w_i}{w_j}$.

According to Theorem 4.1 in [4], the optimum value of the linear program (5)-(10) is 0 if and only if weight vector \mathbf{w} is efficient. Let $(\mathbf{y}^*, \mathbf{s}^*)$ denote the optimal solution to (5)-(10). If weight vector \mathbf{w} is inefficient, then weight vector $\mathbf{w}' = \exp(\mathbf{y}^*)$ is efficient and dominates \mathbf{w} internally.

1.2 Weighting methods

Several weighting methods have been proposed to find a weight vector \mathbf{w} from a pairwise comparison matrix \mathbf{A} . An inevitably oversimplified conclusion of the comprehensive studies of Golany

Given an existing w
vector, ...

and Kress [15], Choo and Wedley [7], Lin [17], Bajwa, Choo and Wedley [2], Fedrizzi and Brunelli [12], is that there is no universal weighting method that outperforms the others.

Several distance minimizing methods, such as the least squares method, where the metric is strictly monotonic [11], always result in efficient weight vectors. Interestingly, not all distance minimizing methods generate efficient weights. The most remarkable example is the eigenvector method, deriving weight from the principal right eigenvector of \mathbf{A} , which minimizes a special (neither continuous, nor strictly monotonic) metric found by Fichtner [13, 14]. Blanquero, Carrizosa and Conde [3] observed first that the eigenvector is not always efficient. However, a necessary and sufficient condition of the efficiency of the eigenvector has not been found.

We show that another two weighting methods, namely the arithmetic mean of weight vectors calculated from all spanning trees and the weight vector calculated by the cosine maximization method can also be inefficient. The spanning tree approach was proposed by Tsyganok [24, 25]. It takes into account all the connected subsets of cardinality $n - 1$ of the set of all comparisons, i.e., all the n^{n-2} spanning trees if the matrix elements are represented by edges in a graph on n vertices. Every spanning tree determines a unique weight vector, and two natural ways of their aggregation are the arithmetic mean [21, 22, 24, 25], denoted here by AMAST (arithmetic mean of all spanning tree weight vectors), and the geometric mean [18, 6]. However, the geometric mean of all spanning tree weight vectors has recently been proved to be equivalent to the Logarithmic Least Squares Method [8, 9, 10, 19], which always provides an efficient weight vector [3, Corollary 7]. The eigenvector and the logarithmic least squares method are equivalent for 3×3 pairwise comparison matrices [8, 9]. Consequently, the smallest matrix size, when the eigenvector can be inefficient, is 4×4 .

The cosine maximization method [16] is based on a geometric intuition of that vectors can be considered similar to each other if their angle is small (cosine of the angle is high), or, equivalently, their dot product is high. The simply computable and unique weight vector [16, Theorem 2], denoted by \mathbf{w}^{\cos} , maximizes the sum of cosine similarity measure for all column vectors of the pairwise comparison matrix. Despite the geometric intuition behind, weight vector \mathbf{w}^{\cos} can be inefficient as it is presented in the next section.

2 Results

There are 1 007 097 pairwise comparison matrices of size 4×4 such that all elements are from the ratio scale $1, 2, \dots, 9, 1/2, 1/3, \dots, 1/9$, and no pair of matrices can be transformed into each other by row/column permutations (without permutation filtering there would be $17^6 = 24\,137\,569$ matrices).

1 Matrices with acceptable inconsistency ($CR \leq 0.1$)

The CR inconsistency is below 0.1 [20] for 32 157 out of all permutation filtered matrices, resulting in a ratio 3.19%. It is similar to the frequency 3.15% experienced by Bozóki and Rapcsák [5, Table 4], although their matrices were generated randomly.

Out of the 32 157 permutation filtered matrices fulfilling $CR \leq 0.1$,

- 591 (1.84%) have inefficient eigenvector;
- 197 (0.61%) have inefficient weight vector calculated by the spanning trees' arithmetic mean;
- 602 (1.87%) have inefficient weight vector calculated by the cosine maximization method.

Itt nem kéne kiemelni,
hogy ez computational
results?

They are listed in the Appendix (Examples A.1–591, B.1–197, C.1–602, respectively), an illustrative example is given below.

Example. (*Example A.73 in the Appendix*)

$$\mathbf{A} = \begin{pmatrix} 1 & 2 & 6 & 7 \\ 1/2 & 1 & 5 & 2 \\ 1/6 & 1/5 & 1 & 2 \\ 1/7 & 1/2 & 1/2 & 1 \end{pmatrix}, \quad \lambda_{\max} = 4.2251, \quad CR = 0.0849$$

$$\mathbf{w}^{EM} = \begin{pmatrix} 0.536063 \\ 0.284402 \\ 0.096706 \\ 0.082830 \end{pmatrix}$$

$$\left[\frac{w_i^{EM}}{w_j^{EM}} \right] = \begin{pmatrix} 1 & 1.8849 & 5.5432 & 6.4718 \\ 0.5305 & 1 & 2.9409 & 3.4336 \\ 0.1804 & 0.3400 & 1 & 1.1675 \\ 0.1545 & 0.2912 & 0.8565 & 1 \end{pmatrix},$$

It can be seen that all non-diagonal elements of the first row/column are under/overestimated, indicating that the eigenvector is inefficient. Indeed, the efficient and internally dominating weight vector \mathbf{w}' , found by (5)-(10) is as follows:

$$\mathbf{w}' = \begin{pmatrix} 0.550771 \\ 0.275385 \\ 0.093640 \\ 0.080204 \end{pmatrix}.$$

Its relation to the eigenvector \mathbf{w}^{EM} can be made more visible by an appropriate rescaling

$$\mathbf{w}' = 0.968297 \cdot \begin{pmatrix} 0.568803 \\ 0.284402 \\ 0.096706 \\ 0.082830 \end{pmatrix},$$

which shows that the last three coordinates have not changed, the first coordinate has been increased as we expected. Furthermore, the first coordinate has been increased such that $a_{12} = \frac{w'_1}{w'_2} = 2$, i.e., not only $\left| \frac{w'_1}{w'_2} - a_{12} \right| < \left| \frac{w_1}{w_2} - a_{12} \right|$ holds but the left hand side of the inequality equals to zero.

$$\left[\frac{w'_i}{w'_j} \right] = \begin{pmatrix} 1 & 2 & 5.8818 & 6.8671 \\ 1/2 & 1 & 2.9409 & 3.4336 \\ 0.1700 & 0.3400 & 1 & 1.1675 \\ 0.1456 & 0.2912 & 0.8565 & 1 \end{pmatrix},$$

We would also like to draw the attention to a special example.

Example 2.1. (*Example A.116 in the Appendix*)

$$\mathbf{A} = \begin{pmatrix} 1 & 2 & 9 & 8 \\ 1/2 & 1 & 3 & 6 \\ 1/9 & 1/3 & 1 & 3 \\ 1/8 & 1/6 & 1/3 & 1 \end{pmatrix}, \quad \lambda_{\max} = 4.1263, \quad CR = 0.0476$$

$$\mathbf{w}^{EM} = \begin{pmatrix} 0.578100 \\ 0.277375 \\ 0.096350 \\ 0.048175 \end{pmatrix}$$

$$\left[\frac{w_i^{EM}}{w_j^{EM}} \right] = \begin{pmatrix} 1 & 2.0842 & 6 & 12 \\ 0.4798 & 1 & 2.8788 & 5.7577 \\ 1/6 & 0.3474 & 1 & 2 \\ 1/12 & 0.1737 & 1/2 & 1 \end{pmatrix},$$

$$\mathbf{w}' = \begin{pmatrix} 0.571429 \\ 0.285714 \\ 0.095238 \\ 0.047619 \end{pmatrix} = 0.988460 \cdot \begin{pmatrix} 0.578100 \\ 0.289050 \\ 0.096350 \\ 0.048175 \end{pmatrix},$$

$$\left[\frac{w'_i}{w'_j} \right] = \begin{pmatrix} 1 & 2 & 6 & 12 \\ 1/2 & 1 & 3 & 6 \\ 1/6 & 1/3 & 1 & 2 \\ 1/12 & 1/6 & 1/2 & 1 \end{pmatrix},$$

The ratios calculated from the dominating weight vector give not only an improved, but a perfect approximation of the original pairwise comparison matrix in all entries of a row/column. Examples A.116, A.139, A.162., A.200, A.374 and A.553 have this particular property.

2.2 Matrices with arbitrary CR inconsistency

Since the rule of thumb $CR \leq 0.1$ has been applied in a wide range of decision problems [23, 26], its theoretical foundation is debated. We have considered all the 1 007 097 permutation filtered pairwise comparison matrices of size 4×4 and plotted the frequencies of inefficient eigenvector, arithmetic mean of all spanning tree weight vectors (AMAST), and the weight vector from cosine maximization, as functions of CR inconsistency. $CR = 0$ represents the consistent case. The upper bound of CR is 3.645 since pairwise comparison matrix

$$\begin{pmatrix} 1 & 9 & 1/9 & 9 \\ 1/9 & 1 & 9 & 1/9 \\ 9 & 1/9 & 1 & 9 \\ 1/9 & 9 & 1/9 & 1 \end{pmatrix}$$

Nekem a max CR 3.67
körfűli (?)

has the largest $\lambda_{\max} = 13.66$, consequently the largest CR inconsistency [1].

The number of pairwise comparison matrices as a function of CR (on the left in Figure 1) is similar to the one in Bozóki, Rapcsák [5, Figure 3b], but their matrices were generated randomly.

The right part of Figure 1 shows that the ratio of inefficient EM, AMAST and cos weight vectors is maximal (29%; 28% and 14%, respectively) at around $CR = 1.2$. All the three methods provide efficient priority vectors for matrices with extremely high inconsistency ($CR > 2.6$).

Ha még idefér, lehet külön kiemelném,

3 Conclusions

We have found that three weighting methods, the eigenvector, the arithmetic mean of all spanning trees's weight vectors and the cosine maximization provide inefficient priority vectors with a small but not negligible frequency if $CR \leq 0.1$. Hundreds of examples indicate that it is not only a theoretical phenomenon, but it may have effect on the ranking itself, too. Our opinion is that inefficient priority vectors are not acceptable in any decision problem. Consequently, the test of efficiency, and, in case of inefficiency, finding an efficient dominating weight vector is necessary.
